Note Although it lacks many of Photoshop's editing tools and is not as robust as Photoshop, Adobe Illustrator is also a great program for designing graphics. Illustrator has a different feel than Photoshop and therefore features many different tools. It uses vector-based tools rather than a pixel-based system, so you have much more control over shapes. You can create very elaborate shapes and use them to create parts of an illustration. * * *Tools panel* *. Photoshop's main toolbox for manipulating pixels is the Tools panel, which lets you access a variety of brushes, gradients, effects, filters, and more. While Photoshop doesn't have as many tools as the other programs mentioned here, it does have many useful tools. Most of the tools found here are covered in detail in the "Using the Photoshop and Illustrator Tools" chapter of the book.

The effect of blood and buffered saline versus unmodified water on pattern formation during blastulogenesis in the sea urchin. For a 2-hour blastula stage, before gastrulation, the two-dimensional cell columns of the embryo are lined with four main groups of cells: (1) oral pole or peristome cells, (2) site of outgrowth of the mouth, (3) ventral site of outgrowth, and (4) posteriolateral cells. Buffered saline and physiologic concentrations of blood had a major effect on pattern formation. The effect of water (unmodified) was minimal. The floor cells are the last group to form in the blastula. There are two explanations for the role of blood. A first interpretation is that the low density of blood and blood cells promotes cell movement into the ventral and oral site of cell outgrowth, at the expense of the dorsal or lateral site of cell outgrowth. An alternative interpretation is that blood is necessary for the formation of a midline site of outgrowth. This interpretation is favored because in controls cultured in unmodified water, the oral cells are often found in the oral pole of the blastula, laterally to the ventral site of cell outgrowth. The second group of cells to form are the ventral and oral pole cells. In controls, the ventral cells form a small patch while the oral pole cells are still dividing. In blood cultures, the ventral cells form a larger patch with a midline of in-growth, while the oral pole cells divide vigorously, despite the presence of blood cells. Since the second group of cells to form are the oral pole cells, water and unmodified water (i.e., water which contains the normal concentrations of ions and nutrients) will not interfere with the normal sequence of cell differentiation during the blastula stage.
